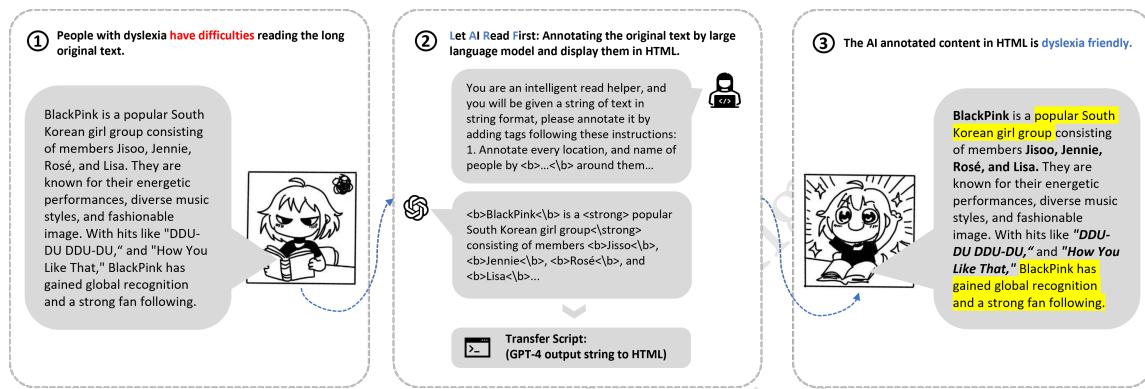

Fig. 1. People with dyslexia always have difficulties while reading. We propose a method Let AI Read First (LARF) that uses language models to annotate the original text and display them in HTML format. Our experiment validates that LARF can improve reading performance and improve the reading experience for individuals with dyslexia.

Dyslexia, a neurological condition affecting approximately 12% of the global population, presents significant challenges to reading ability and quality of life. Existing assistive technologies are limited by factors such as unsuitability for quiet environments, high costs, and the risk of distorting meaning or failing to provide real-time support. To address these issues, we introduce LARF (Let AI Read First), the first strategy that employs large language models to annotate text and enhance readability while preserving the original content. We evaluated LARF in two large-scale between-subjects experiments, involving 150 participants with dyslexia and 160 participants from the general population. The results show that LARF significantly improves reading performance and experience for individuals with dyslexia. Results also prove LARF is particularly helpful for participants with more severe reading difficulties. Furthermore, our work proposes design guidelines and discusses potential research directions opened up by LARF for the HCI community.

60 Individuals with Dyslexia through Artificial Intelligence. In *Proceedings of Make sure to enter the correct conference title from your rights*
61 *confirmation emai (Conference acronym 'XX)*. ACM, New York, NY, USA, 28 pages. <https://doi.org/XXXXXXX.XXXXXXXX>
62

63 **1 Introduction**
64

65 Dyslexia constitutes a category of neurodevelopmental impairments that affect reading abilities, typically manifested
66 as challenges to reading fluency, speed, and comprehension. Such disabilities can significantly impact the lives and
67 learning of affected individuals [1, 2]. Approximately 12% of the global population has dyslexia [3]. Individuals with
68 dyslexia often struggle with word decoding and recognition, which also affects their comprehension, fluency, and
69 vocabulary. This condition leads to academic difficulties and increases the risk of bullying in children and adolescents
70 [4]. Additionally, adults with dyslexia commonly experience considerable deficits in executive functioning [5]. Current
71 interventions, mainly in the form of accessible designs, tend to focus on only a few areas: converting text to speech
72 [6], videos or games [7, 8], adjusting text font through electronic readers [9, 10] (e.g., character size, colour, spacing
73 between words), and replacing complex words with simpler synonyms [11]. Nevertheless, these efforts often exhibit
74 one or more of the following limitations:
75

- 76 (1) In scenarios demanding quiet, such as conferences and exams, the use of multimedia-assisted tools presents
77 practical difficulties due to their limited applicability.
78 (2) Manual annotation relies heavily on human effort. Converting text descriptions into videos or games manually
79 can be both expensive and non-real-time.
80 (3) Simple synonym substitution and rewriting can sometimes alter the original meaning and compromise the
81 aesthetic qualities of the original texts (e.g., emotions, rhymes).
82

83 Compared to the available knowledge about reading difficulties and the demonstrated capabilities of Artificial
84 intelligence (AI) models, there are relatively few accessible designs that effectively address these challenges [12]. With
85 the rapid development of AI [13], especially in natural language processing(NLP) [14], numerous spelling assistance
86 tools for dyslexia have demonstrated considerable capabilities [15, 16]. However, we have not yet discovered any
87 existing reading assistance tools or research that has utilised or discussed how to integrate state-of-the-art AI techniques
88 to address these issues in assistive reading tools for people with dyslexia.
89

90 Therefore, to fill these gaps, we propose an AI-based presentation strategy to assist people with dyslexia in reading.
91 We introduce LARF (Let AI Read First), an AI-based method that annotates “important” information in texts with
92 highlights, bolding, underlining, and other marks. This approach aims to help readers focus more easily on the key
93 content of the original text, thereby enhancing their reading performance and experience. Unlike direct AI-generated
94 summaries, LARF’s design of annotating the original text preserves the maximum amount of original textual information.
95

96 Our main hypothesis is that LARF can improve the overall reading performance and experience of people with
97 reading difficulties. Consequently, we conducted two large-scale experiments to evaluate this hypothesis.
98

99 We first conducted Experiment One ($N = 150$) in which participants were from the United Kingdom and the United
100 States and self-reported as having dyslexia, all of whom had English as their mother tongue. Participants were divided
101
102 Manuscript submitted to ACM

105 into three groups. The groups included: a control group that read the original reading materials directly, a conventional
106 group in which participants read the same materials processed by Bionic Reading [17], and a LARF group that the
107 reading materials are annotated by OpenAI's GPT-4 [18]. We tested the accuracy in recalling and retrieving details,
108 and comprehension levels, using multiple-choice questions. The experimental results show that participants who read
109 GPT-4-annotated texts demonstrate better recall and retrieval performance compared to those using traditional methods
110 and the control groups. Participants were also asked to complete a series of subjective evaluations to assess their user
111 experience with LARF or the conventional tool. The results indicate that LLM-annotated texts significantly improve
112 perceived user-friendliness, overall satisfaction, perceived helpfulness, future use, and recommendation tendencies.
113 Users also believe that this method should be applied as a text presentation method for dyslexic populations in more
114 scenarios (e.g., exams, accessible website design).

115 Given that dyslexia is a spectrum disorder, we designed Experiment Two ($N = 160$) to examine whether LARF is also
116 helpful for individuals in the general population who may experience varying degrees of reading difficulties (from none
117 to severe), but have not necessarily self-identified as dyslexic. We conducted a similar experiment to that in Experiment
118 One, involving 160 participants from the United States. We observed similar results and found that LARF is more helpful
119 for individuals with more severe reading difficulties.

120 In summary, our main contributions are:
121
122 • We propose LARF, the first method to leverage LLMs for text annotation, improving text accessibility for
123 individuals with reading difficulties.
124 • We conducted two large-scale between-subjects experiments, involving participants with reading disabilities($N =$
125 150) and from the general population($N = 160$), to validate the effectiveness of LARF. Additionally, we found this
126 tool to be particularly beneficial for individuals with severe reading disabilities.
127 • We suggest future research directions based on LARF for the HCI community.

128 2 Related Work and Background

129 2.1 Reading Assistance Tools for Dyslexia

130 In the realm of accessible design interventions to alleviate reading difficulties, myriad solutions have been proposed. A
131 popular trend has been to incorporate text-to-speech conversion [6], enabling individuals with reading difficulties to
132 access written content orally. Parallelly, innovative efforts have been made to employ multimedia elements such as
133 videos and games to facilitate reading comprehension [7]. However, these software solutions often face environmental
134 constraints. In scenarios necessitating quietness, such as conferences or exams, the use of text-to-speech conversion
135 is impractical. Moreover, despite proven effectiveness [19, 20], the high cost of software like Kurzweil3000 limits its
136 widespread adoption [19]. Furthermore, traditional methods of transforming textual information into images, audio, or
137 even games require substantial involvement from experienced annotators, developers, and designers. This significantly
138 escalates costs and eliminates the possibility of real-time use, thus further restricting its application scenarios.

139 The other trend is using adjustable text presentation, allowing for modifications in character size, colour, and word
140 spacing [9, 10]. Santana et al. [21] created Firefixia, which is a browser extension that enables dyslexic readers to tailor
141 websites for enhanced readability. Text4All [22], an online service for web pages, and the Android IDEAL eBook reader⁴
142 for e-books are customisation tools informed by previous research in dyslexic individuals [9]. Text4All extends its
143 offerings to include medical language adaptation, terminology annotation, and language analysis. Currently, a popular
144 method called Bionic Reading [17] revises texts so that the most concise parts of words are highlighted. This guides
145

157 the eye over the text, and the brain remembers previously learnt words more quickly. Although these methods can
 158 be applied in a broader range of contexts, they treat all text as a uniform entity, lacking a targeted emphasis on key
 159 segments such as definitions or summary sentences. This results in substantial room for improvement to improve
 160 reading performance and experience.
 161

162 "In another approach, complex words are replaced with simpler synonyms to aid comprehension [11]. However,
 163 such an approach not only fails to guarantee accuracy in the context of substitution (i.e., it may completely distort the
 164 original intent of the text) but may also affect the literary attributes of the text, such as emotional intensity and rhythm.
 165

166 Despite the wealth of knowledge surrounding reading difficulties, traditional accessible designs addressing these
 167 challenges remain limited [12]. Considering the rapid advancements in AI, the incorporation of AI models with superior
 168 reading comprehension and creativity into accessible design offers a promising area for further exploration. As these
 169 models become increasingly versatile and powerful, their intersection with accessible design presents a promising
 170 opportunity to overcome the limitations of current solutions.
 171

172 2.2 Language Models

173 In recent years, the rapid development of artificial intelligence (AI) technology has been evident [13], with the ad-
 174 vancement of natural language processing (NLP) tasks, specifically language models (LMs) [23–26], being particularly
 175 prominent. Despite the intricate structures and profound mathematical foundations underlying language models, they
 176 can essentially function as a "simple" black box, processing input text to generate appropriate output for the given task
 177 [14].
 178

179 ChatGPT [18], published by OpenAI, is the successor to InstructGPT [27], fine-tuned using Reinforcement Learning
 180 with Human Feedback (RLHF) [28], and has gained phenomenal attention and widespread discussion not only within
 181 the NLP community but also globally. In this paper, we used GPT-4 to generate re-formatted content that is more
 182 friendly for individuals with reading challenges. However, we do not discuss the theoretical background or technical
 183 details.
 184

185 HTML tag	186 Description	187 Example
188 	189 Bold the text	190 Example
191 <i>	192 Italicize the text	193 Example
194 <u>	195 Underline the text	196 Example
197 	198 Highlight the text	199 Example
200 ...	201 ...	202 ...

203 Fig. 2. An example of the different HTML tags and their display result in HTML format. It is worth noting that in practical programming
 204 environments, the display of HTML tags can be highly diverse, including adjustments to font, text colour, highlighting colours, etc.
 205 The figure provides examples of only a few common default tags and their display results.
 206

207 2.3 Hyper Text Markup Language (HTML)

208 In Hyper Text Markup Language (HTML) [29, 30], various tags can be used to manipulate the display of text, such
 209 as "bold," "highlighting," "italics," changing font colour, and adjusting font size. For instance, the "<\b>" tags can
 210 display text in bold as shown in Figure 2. We can modify the appearance of text without changing its content by using
 211 Manuscript submitted to ACM

209 HTML tags. In real-world scenarios, HTML can produce diverse visual effects; however, in this work, we focus only on
210 fundamental HTML tags.
211

212 3 Method and Data

213 3.1 Workflow of LARF

214 The workflow of LARF is illustrated in Fig. 1, in which the original text is input as a string. Guided by preset prompts,
215 GPT-4 processes the original text, incorporating the HTML tags. The resulting HTML-tagged text is output as a new
216 string. Subsequently, a Python script compiles this HTML-tagged string into an HTML file, serving as the final output.
217 Consequently, users receive a presentation where specific information has been modified with bold formatting or
218 highlighting, while the textual content remains entirely unchanged. The simple example in Fig. 1 shows a segment taken
219 from Wikipedia about BlackPink [31]. GPT-4 was asked to highlight sentences that serve a summarizing role using
220 `<mark></mark>` tags. It also asked to bold important names of people and items using `` tags. After processing
221 the output of GPT-4 with the transfer scripts, the user gets the GPT-4-annotated content shown on the right-hand side.
222

223 In subsequent experiments and practical applications, we adjusted the prompts by using different labels, thereby
224 modifying the presentation of the text. The detailed default prompts can be found in the Appendix A.6.
225

226 3.2 GPT-4 Data

227 In Experiment One and Experiment Two, we processed the reading materials using GPT-4 API. We also used GPT-4
228 together with human evaluation to score the participants' short-answer questions in subsequent experiments. The
229 version of GPT-4: ChatGPT July 20 version. We set the temperature as 0 to ensure the result is reproducible. All the
230 specific prompts and generation logs can be found in the supplement material and Appendix.
231

232 3.3 Bionic Reading Data

233 We employed the Bionic Reading [17] as a representative of conventional tools to process the corpora in subsequent
234 experiments, as it is one of the most widely used reading performance improvement solutions. "Fixation" defines the
235 expression of the letter combinations. It can be set as a value from 1 to 5. We use 3, which is also the default value. With
236 "Saccade" we can define the visual jumps from fixation to fixation. It can be set as a value from 10 to 50. In this paper,
237 we also apply the default value of 10.
238

239 An Example of Bionic Reading

240 BlackPink is a popular South Korean girl group consisting of members Jisoo, Jennie, Rosé,
241 and Lisa. They are known for their energetic performances, diverse music styles, and
242 fashionable image. With hits like "DDU-DU DDU-DU," and "How You Like That," BlackPink
243 has gained global recognition and a strong fan following.
244

245 4 Ethic & Transparency

246 4.1 Ethics

247 The experiments involved in this work have been approved by the Institutional Review Board (IRB) of our affiliation.
248 All the participants in Experiment 1 and Experiment 2 were recruited through the Prolific platform and completed
249 informed consent forms. All of the participants in Experiment 3 were from a neurodivergent community in China, who
250 voluntarily participated in the software experience activity and they were also informed consent forms.
251

261 4.2 Transparency

262 All raw experimental data, GPT-4 processing history (including evaluations and annotations), and data analysis code
263 are available in the supplementary materials. Examples of our prompts and questions in the questionnaires are provided
264 in Appendix A. The LARF demo is publicly available for free trials.
265

266 5 Experiment One: LARF’s Effectiveness among Dyslexia Participants

267 The primary objective of the first experiment is to validate our main hypothesis, namely, whether LARF, compared to
268 traditional methods (i.e., Bionic Reading) and control groups, can improve reading performance and to what extent
269 it affects the reading experience of individuals with dyslexia. We evaluated both reading performance and reading
270 experience using objective measures and subjective evaluations.
271

272 5.1 Experiment Setup

273 In this experiment, we focus on English speakers, as English is the world’s most spoken language and the third most
274 spoken native language[32]. Large language models such as GPT-4 predominantly utilize English in their training data,
275 and consequently, their performance is most proficient when processing English text[33].
276

277 We chose Reading Test 115, Passage 2, “The Step Pyramid of Djoser,” a descriptive and factual reading text from the
278 IELTS[34] Academic as the corpus in this study. This decision was motivated by the comprehensive nature of the IELTS
279 Academic reading test, which employs a long-form format featuring texts sourced from books, journals, magazines,
280 and newspapers[35]. We chose this test to scrutinize participants’ reading efficiency for several reasons. Firstly, the
281 descriptive and factual text provides comprehensive and verifiable information about a subject[36]. Secondly, the IELTS
282 Academic test is equipped with expertly formulated questions and standardized answers. These questions’ careful
283 design and standardization add another layer of reliability and validity to our study, making the IELTS Academic test a
284 proper tool for assessing adult reading performance.
285

286 5.2 Method and Experiment Procedure

287 We recruited our participants from Prolific[37]. Prolific is an online research platform that connects researchers with
288 a diverse participant pool for academic studies, surveys, and experiments. 150 individuals who have been medically
289 diagnosed with dyslexia, are in the process of being diagnosed, or strongly suspect they have undiagnosed dyslexia
290 participated in our study ($M_{age} = 36.8$, 33.3% Female). Details about participants’ demographics can be found in
291 Appendix A.1. Participants were randomly assigned to one of three experimental conditions: the control condition,
292 the conventional tool condition, or the LARF condition. In the control condition, the article was presented without
293 any modifications or annotations. In the conventional tool condition, modifications of the article were based on the
294 Bionic Reading Method. Lastly, in the LARF condition, the article was annotated by GPT-4. Participants were not
295 pre-informed that texts in the LARF group are annotated by GPT-4, nor was the rationale behind annotations (e.g.,
296 bolding of significant characters’ names) disclosed. While this approach may attenuate the effects of LARF, it mitigates
297 the influence of psychological priming on the results.
298

299 The study began with participants completing a Dyslexia Checklist (refer to Appendix A.3), designed to assess the
300 severity of various reading-related challenges they face based on personal experiences. Afterwards, they read an article
301 and answered a series of recall questions to evaluate their retention of key details, such as the main character’s name
302 and aspects of a described pyramid. Our design included six recall questions, alongside an attention check question
303 304
305 306
307 308
309 310
311 312

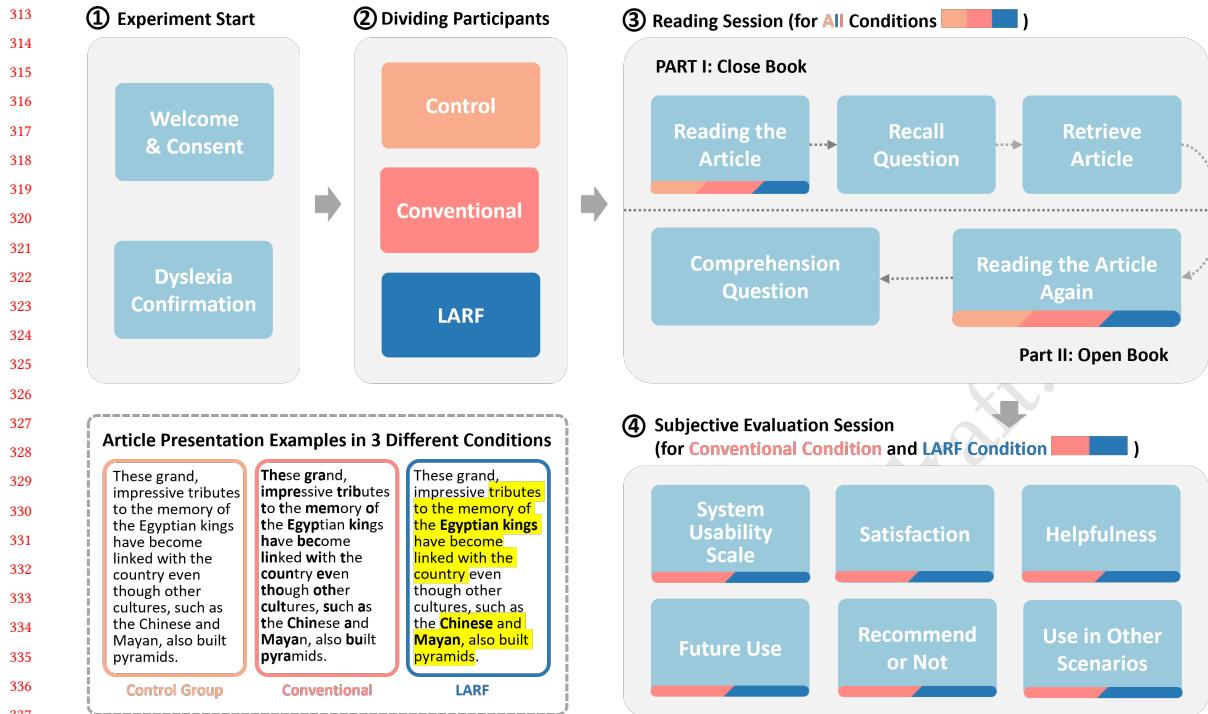

Fig. 3. Experiment Procedure. Participants are randomly assigned to three conditions, and then they are asked to finish the reading session. They are required to read the same article but with different presentations. Participants in the conventional condition group and LARF condition group are required to finish a subjective evaluation session after they finish the reading session.

(refer to Appendix ??). Following the recall task, participants were asked to retrieve as many details from the article as possible. The article was then presented, immediately followed by a reading comprehension assessment on the same page.

After reading, participants in the control condition provided demographic information (age, gender, educational background) and completed the experiment. Participants in the conventional tool and LARF conditions also evaluated the modifications and annotations made by these tools. We used an adapted version of the System Usability Scale[38] to assess tool usability. Participants then rated the tool's perceived helpfulness, satisfaction, intention to continue using it, and likelihood of recommending it to others. Participants in the conventional tool condition completed the experiment after providing demographic information. In contrast, participants in the LARF condition were asked about their preference for a personalized LARF tool before providing demographic information. The experimental procedure and session details are shown in Fig. 3.

5.3 Result and Analysis

Attention Check: Of the initial 150 participants, 2 failed to pass the attention check and were consequently excluded from further analysis. The remaining 148 participants were included in subsequent analyses. There are 51 participants in the control condition, 49 in the conventional tool condition, and 48 in the LARF tool condition. The detail of the attention check is given in the Appendix A.2.

Dyslexia Checklist: Before reading the article, participants assessed their own dyslexia levels using the Dyslexia Checklist (see Appendix A.3 for Dyslexia Checklist). This checklist comprises six items that evaluate various aspects: comprehension issues, word recognition difficulties, decoding difficulties, memory problems, attentional difficulties, and visual disturbance. We calculated the average scores from these items to determine each participant's overall dyslexia level (Cronbach's alpha = 0.91). Statistical analysis reveals no significant differences in dyslexia levels across the three conditions ($M_{control} = 3.80, SD = 1.65$, $M_{conventional} = 3.48, SD = 1.41$; $M_{LARF} = 3.49, SD = 1.29$; $F(2, 145) = .755$, $p = .472$), which indicates that participants are balanced among three conditions

Reading Time: We initially focused on the time participants took to read the passage before the recall section, using this as the primary measure of reading time. Ten participants are identified as outliers based on their initial reading times (defined as initial reading time $> Q3 + 1.5 \times IQR$ or $< Q1 - 1.5 \times IQR$) and were thus excluded from this part of the analysis. Consequently, the final analysis on reading time is conducted with 138 participants. Covariates including education, age, gender, and dyslexia level are considered in the analysis. The one-way ANOVA shows no significant differences in reading times across conditions ($M_{control} = 117.56, SD = 46.47$; $M_{conventional} = 122.57, SD = 62.70$; $M_{LARF} = 118.26, SD = 50.69$; $F(2, 135) = .160, p = .853$). However, considering the first corpus' length of 388 words, and average reading speeds of 238 words per minute for English readers[39], those who spend less than 30.2 seconds (0.05 quantile) are considered relatively impatient. Fig. 4(a) shows that participants using LARF do not fall below 30 seconds and are concentrated within a shorter, reasonable range. This suggests that LARF may aid in attracting user attention and enhancing reading patience and confidence.

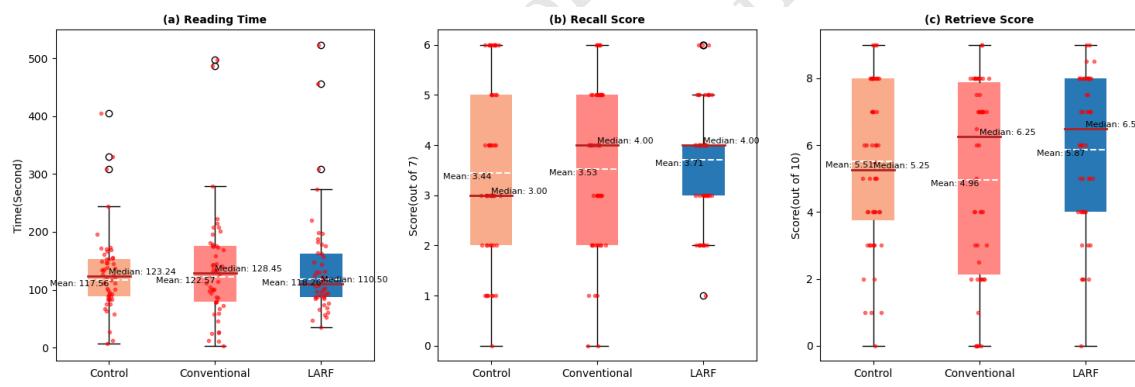

Fig. 4. (a) shows the differences in reading time under three different conditions. Though the pattern is not significant, we can observe that users in the LARF group do less "glance over and skip the article." Furthermore, their overall reading time is more concentrated in areas with shorter durations. Subfigure (b) and (c) respectively represent the scores of users in the retrieve and recall phases. It can be observed that compared to other groups, participants reading the LARF-marked texts exhibit better recall ability (marginally significant) and a superior capability to remember the details of the articles (significant).

Recall Performance: In the recall section, participants are asked six questions (example questions can be found in Appendix A.4), earning one point for each correct answer. For this part of our analysis, we include education, age, gender, dyslexia level, and reading time as covariates in the one-way ANOVA analysis. The result Fig. 4b reveals that participants in the LARF condition tend to score higher (7.8% higher than the control group and 5.1% higher than conventional group) than the other two conditions, though the difference was not statistically significant ($M_{control} = 3.44, SD = 1.74$, $M_{conventional} = 3.53, SD = 1.64$; $M_{LARF} = 3.71, SD = 1.20$; $F(2, 128) = .215, p = .807$).

417 **Retrieve Performance:** Following the recall section, participants were instructed to retrieve as many details from
418 the article as possible (example question can be found in Appendix A.5.) We employ GPT-4 to evaluate the quality
419 of participants' retrieval performance, utilizing a scoring range of 0 to 10. The assessment scores of GPT-4 for 148
420 participants underwent verification by two human reviewers, each of whom independently cross-checked the scores.
421 The reviewers made only one significant correction to the scores, which was clearly erroneous. The scoring criteria
422 can be found in Appendix A.7 and the GPT-4 score logs are available for reference in the supplementary materials. A
423 similar one-way ANOVA analysis was conducted. The results in Fig. 4c clearly show a significant difference across
424 three conditions ($F(2, 128) = 3.465, p = .034$). Participants in the LARF condition ($M_{LARF} = 5.87, SD = 2.30$) scored
425 higher (6.5% higher than the control group and 18.3% higher than the conventional group) than the other two conditions
426 ($M_{control} = 5.51, SD = 2.38, M_{conventional} = 4.96, SD = 2.89$).
427

428 **Comprehension Performance:** In our study, the final objective measure was reading comprehension, assessed
429 using a method analogous to that employed in the IELTS examination. Participants were required to identify the correct
430 two statements out of six that were presented in the article. To ensure accuracy in scoring, participants selecting more
431 than two statements were automatically assigned a score of zero, as per our predefined criteria that only two statements
432 were correct.
433

434 Our analysis revealed that 72.92% (35/48) of participants in the LARF condition correctly chose the exact two
435 statements. In contrast, this accuracy was observed in 64.71% (33/51) of participants in the control condition and 67.35%
436 (33/49) in the conventional condition. Additionally, we evaluated whether participants were able to identify at least one
437 correct statement. In this regard, 100% (48/48) of participants in the LARF condition succeeded in choosing at least one
438 correct statement, whereas the corresponding figures were 92.16% (47/51) for the control condition and 87.76% (43/59)
439 for the conventional condition. We conservatively believe that this indicates LARF can to some extent enhance the
440 participants' reading comprehension skills.
441

442 **Subjective Evaluation:** We conducted a separate analysis to compare the subjective evaluations of the annotation
443 tools between the conventional and LARF conditions. The questionnaire items and corresponding results
444 are presented in Fig. 5. **Overall, participants in the LARF condition rendered more favourable evaluations
445 than those in the conventional condition.** Notably, participants exposed to LARF-generated annotations reported
446 more positive perceptions and future behaviour tendencies across multiple dimensions. These included system us-
447 ability ($M_{conventional} = 4.09, SD = 1.42; M_{LARF} = 4.43, SD = 1.36; F(1, 95) = 1.469, p = .229$), satisfaction of the
448 tool ($M_{conventional} = 3.76, SD = 1.92; M_{LARF} = 4.42, SD = 1.84; F(1, 95) = 2.994, p = .087$), perceived helpful-
449 ness ($M_{conventional} = 3.14, SD = 1.76; M_{LARF} = 4.29, SD = 1.99; F(1, 95) = 9.104, p = .003$), intention for fu-
450 ture usage ($M_{conventional} = 2.94, SD = 1.89; M_{LARF} = 3.92, SD = 2.01; F(1, 95) = 6.111, p = .015$), recommend
451 ($M_{conventional} = 3.18, SD = 1.87; M_{LARF} = 4.42, SD = 1.97; F(1, 95) = 10.034, p = .002$), and widespread usage
452 ($M_{conventional} = 3.69, SD = 2.10; M_{LARF} = 4.96, SD = 1.96; F(1, 95) = 9.388, p = .003$). The detailed questions and
453 results are shown in Table 5 and Table 6 in Appendix A.8. **The result suggests that participants in the LARF group
454 show more overall satisfaction, they also reported that LARF is more helpful and easier to use compared to
455 Bionic Reading.**
456

457 Specifically, participants in the LARF condition expressed a favourable inclination towards customizing the LARF
458 tool. This preference was quantitatively reflected, with the mean score for the desire to customize LARF being 5.04 (SD
459 = 1.41).
460

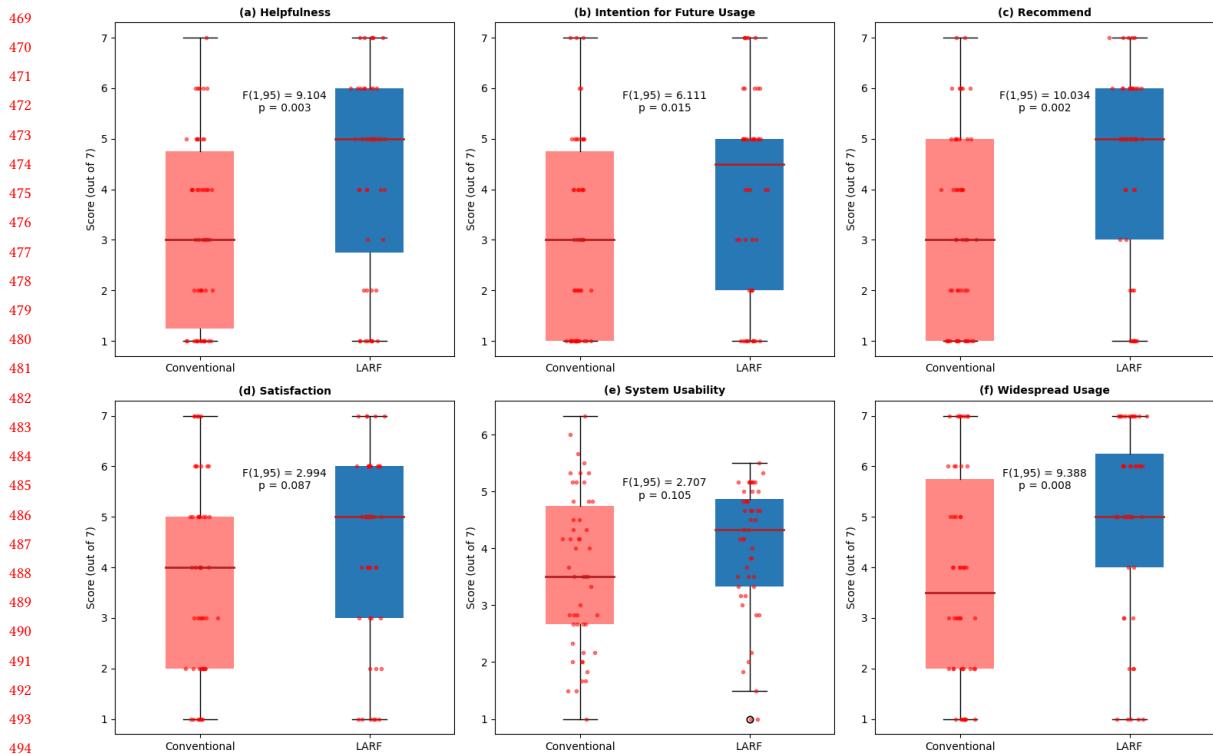

Fig. 5. The subjective evaluation result. Participants with dyslexia exhibited a clear preference for LARF, considering text annotated with LARF to be effective, user-friendly, and worthy of broader adoption in various contexts.

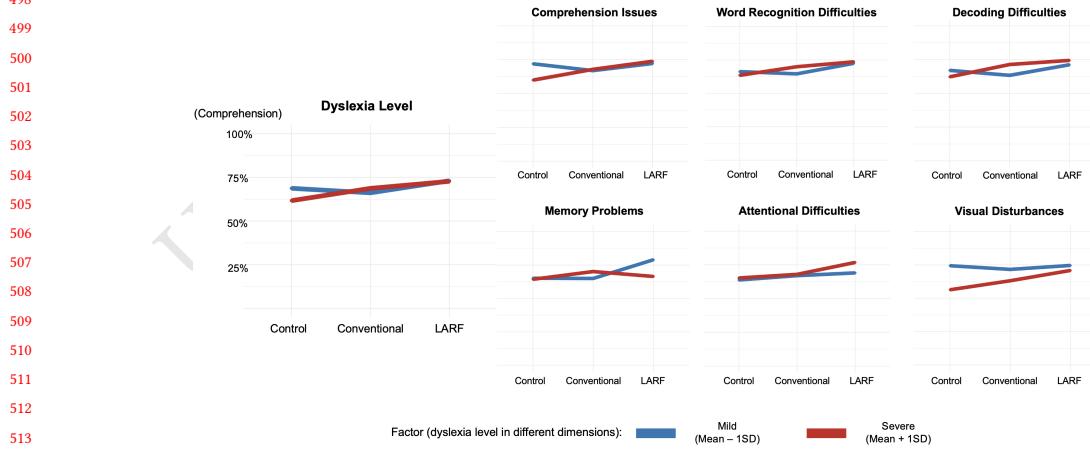

Fig. 6. Post hoc evaluation for comprehension performance. The y-axis represents the accuracy of reading comprehension. In the group with severe symptoms, LARF exhibited significant improvement compare to the conventional group and control group.

521 5.4 Post Hoc Evaluation

522 People with dyslexia often experience different subsets of challenges [40]. Given the varying severity of dyslexia among
523 participants, resulting in distinct reading challenges, we conducted a post hoc evaluation to assess LARF's efficacy
524 across different degrees and categories of reading difficulties, focusing on its effects on various symptoms of reading
525 disabilities. Based on previous research, we calculated the mean ± 1 standard deviation (SD) for each dyslexia item.
526 Participants whose self-reported dyslexia scores were higher than $M + 1$ SD were classified as having severe dyslexia,
527 while those with scores lower than $M - 1$ SD were classified as having mild dyslexia. **Results show that LARF is**
528 **especially helpful for participants with severe dyslexia.** As Fig. 6 shows, the improvement in participants' reading
529 performance is more pronounced in those with severe dyslexia. Similar results can also be observed in their recall (Fig.
530 13) and retrieval (Fig. 12) performance.

534 6 Experiment Two: LARF Effectiveness among General Population

535 As dyslexia is a spectrum disorder, people in the general population may also face challenges during reading. Building
536 on the insights from Experiment One, which focused on dyslexic participants, Experiment Two expands the scope of
537 our investigation to the general population. We aim to understand how the effectiveness of these tools varies across
538 different reader profiles. Similar to the previous experiment, we assess both objective measures (e.g., reading speed,
539 efficiency, and completion rates) and subjective evaluations (e.g., perceived tool helpfulness, and future usage). We
540 recruited 160 participants from Prolific without filtering any information about dyslexia, ensuring a diverse sample
541 representative of the general population.

542 6.1 Method and Experiment Procedure

543 The procedure in Experiment Two mirrors that of Experiment One to maintain methodological consistency. 160
544 individuals on Prolific participated in our study ($M_{age} = 40.6$, 48.13% Female). Detailed information about participants
545 can be found in Appendix A.1. Participants were randomly assigned to one of three experimental conditions: control
546 condition, conventional tool condition, or LARF annotation condition. We used the same article in Experiment One.
547 Initially, participants were presented with a Dyslexia Tendency Adult Checklist [41], a tool designed to assess dyslexia
548 tendencies based on personal experiences. Subsequently, they were in similar reading sessions and evaluation sessions
549 as participants in Experiment One. Based on the attention check and the participants' answers, we were able to identify
550 and exclude participants who appeared to have cheated or provided random responses (e.g., some participants copied
551 the original text of our reading materials and directly pasted it in the retrieval section and some of them use less than
552 10 seconds to finish all the reading and questions.) Out of the initial 160 participants, 22 were consequently disqualified,
553 resulting in a final sample of 138 participants for the performance analysis.

554 6.2 Result and Analysis

555 **Dyslexia Adult Checklist:** The mean dyslexia score for the sample was 32.68, with a standard deviation of 8.17, which
556 means only 14 participants exhibited symptoms aligned with moderate, or severe dyslexia according to the criteria
557 outlined in the Adult Dyslexia Test. We opted to treat the dyslexia score as a continuous variable in subsequent analyses.

558 **Reading Time:** In a manner akin to Experiment One, we conducted a statistical analysis of the time expended by
559 users during their initial reading phase. Out of 148 participants, 10 were excluded based on this criterion, leaving 138
560 for subsequent analysis. Mirroring the approach in Experiment One, we controlled for variables including education,

age, gender, and level of dyslexia. A one-way ANOVA was performed to compare reading times across conditions. The result indicate no significant differences ($M_{control} = 104.33, SD = 58.38, M_{conventional} = 125.94, SD = 70.25; M_{LARF} = 109.22, SD = 62.82; F(2, 129) = 1.510, p = .225$), between conditions. However, the same pattern can be observed that participants in the LARF group are concentrated within the shorter time intervals and also with a lower median reading time.

Recall Performance: Participants were asked seven questions in the recall section this time, earning one point for each correct answer. For this part of our analysis, we included education, age, gender, dyslexia level, and reading time as covariates in the one-way ANOVA analysis. The result reveals that participants in the LARF condition scored marginally higher than the other two conditions ($M_{control} = 5.26, SD = 1.47, M_{conventional} = 5.15, SD = 1.89; M_{LARF} = 5.37, SD = 1.74; F(2, 128) = 1.016, p = .365$).

Retrieve Performance: We used the same method as Experiment 1 to evaluate participants' retrieve performance by GPT-4. A similar one-way ANOVA analysis was conducted. The results showed that participants in the LARF condition ($M_{LARF} = 7.67, SD = 1.64$) scored higher than the other two conditions ($M_{control} = 7.10, SD = 2.17; M_{conventional} = 7.20, SD = 2.31$). But the differences are not significant, either in the base model ($F(1, 135) = .985, p = .376$) and control model (i.e., controlling for dyslexia score, education level, age, and gender; $F(1, 128) = .480, p = .620$).

Comprehension Performance: The final measure for objective outcomes in our study was reading comprehension, evaluated using questions analogous to those in the IELTS examination. Our analysis did not reveal statistically significant differences in reading comprehension performance across three conditions ($M_{control} = 4.20, SD = 2.03; M_{conventional} = 4.02, SD = 1.84; M_{LARF} = 4.12, SD = 1.51$), neither in the base model ($F(2, 145) = .127, p = .881$) nor in the control model ($F(2, 138) = .288, p = .750$).

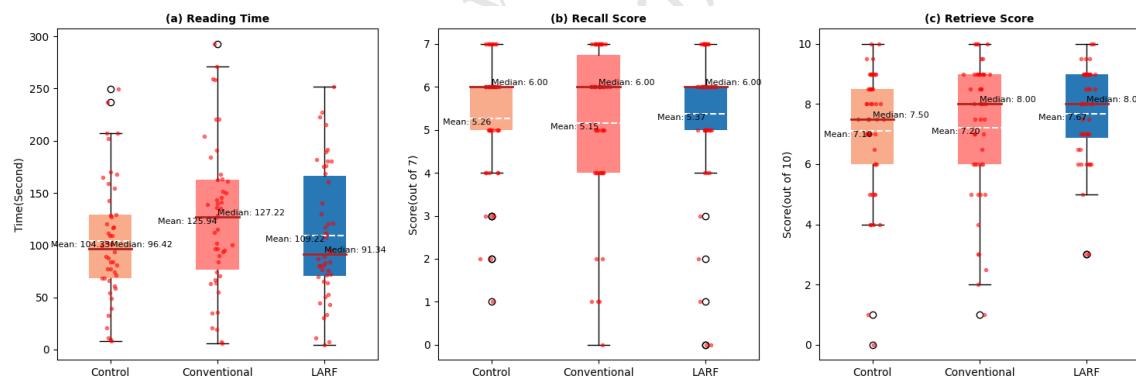

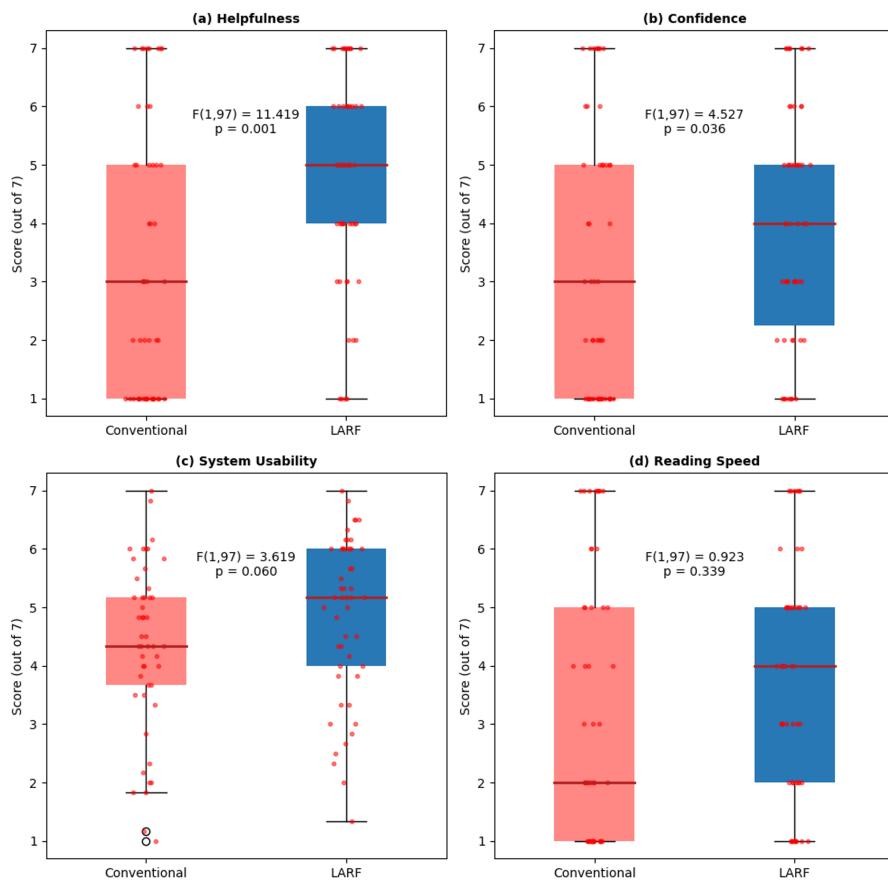

Fig. 7. illustrates that there is no significant difference in performance between the LARF group and the control group in typical readers, despite the median time spent by the LARF group being notably lower compared to the other two groups. (b) and (c) respectively reflect the performance of the general population in the recall and retrieval tasks. Overall, in typical readers, the improvement in the LARF group is not as significant as the improvement observed in individuals with dyslexia in Experiment 1.

Subjective Evaluation: Similar to Experiment One, we conducted a separate analysis to compare the subjective evaluations of the annotation tools between the conventional and LARF conditions. The questionnaire items and completed corresponding results are presented in the supplementary material. A selection of some prominent phenomena is shown in Fig. 8. **Overall, participants in the LARF condition rendered more favourable evaluations than those in the conventional condition, replicating the findings in Experiment One.** Notably, **participants exposed to**

625 **LARF annotations reported significantly more positive perceptions and future behaviour tendencies across**
 626 **multiple dimensions.** These included system usability ($M_{conventional} = 4.33, SD = 1.45; MLARF = 4.87, SD =$
 627 $1.39; F(1, 97) = 3.619, p = .060$), perceived helpfulness of the annotations ($M_{conventional} = 3.29, SD = 2.31; MLARF =$
 628 $4.70, SD = 1.83; F(1, 97) = 11.419, p = .001$), outcomes of the annotation integration ($M_{conventional} = 3.74, SD =$
 629 $1.95; MLARF = 4.58, SD = 1.90; F(1, 97) = 4.795, p = .031$), confidence in reading ($M_{conventional} = 4.59, SD =$
 630 $2.19; MLARF = 4.86, SD = 1.98; F(1, 97) = 4.527, p = .036$), and intention for future usage ($M_{conventional} = 2.98, SD =$
 631 $2.13; MLARF = 3.86, SD = 1.99; F(1, 97) = 4.527, p = .036$).
 632
 633

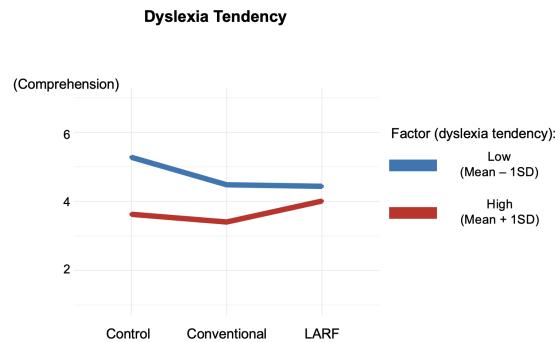

667 Fig. 8. The subjective evaluation shows typical readers also hold a significant positive attitude toward LARF (e.g. participants believe
 668 LARF can help them read faster and is easy to use).

672 In summary, we did not observe a direct significant improvement in reading performance with LARF in the general
 673 population from the result of the objective evaluation. However, in the subjective evaluation, participants show a
 674 positive perception of LARF, suggesting a favourable reading experience for LARF users.
 675

677 6.3 Post Hoc Evaluation

678
 679 The results of Experiment Two on the general population showed that although the LARF group exhibited a trend of
 680 better reading performance compared to the other two groups, the difference was not statistically significant. Given that
 681 the results of Experiment One indicate that LARF is more effective for individuals with more severe reading difficulties,
 682 we conducted a post hoc evaluation similar to that in Experiment One. The results in Fig. 9 and Table. ?? also shows
 683 that LARF is more effective for participants with higher dyslexia tendencies when they are doing retrieval tasks and
 684 reading comprehension tasks in the general population. We coded the control condition as a baseline and centred the
 685 dyslexia scores around their mean. We controlled for demographic variables and time spent on the retrieval task to
 686 isolate the impact of our experimental conditions. Results also show that the **interaction effect between the LARF**
 687 **condition and dyslexia is both positive and statistically significant** ($b = .111, SE = .051, t = 2.182, p = .031$). This
 688 demonstrates that the negative impact of dyslexia on retrieve performance is mitigated in the LARF condition relative
 689 to the control condition. In simpler terms, **when dyslexia scores are higher, being in the LARF condition (vs. the**
 690 **control condition) exerts a more positive influence on retrieve performance.**

691
 692 We didn't replicate this effect when we considered recall performance, which may be because the recall questions
 693 from IELTS are too easy for typical readers whose first language is English. However, when we compare users with recall
 694 scores above the average score, we observe that participants in the LARF group spent significantly less time than those
 695 in the control and conventional groups and the difference is also statistically significant ($F(2, 70) = 3.914, p = .024$.)

700 Fig. 9. LARF significantly improved reading comprehension in participants self-reporting higher dyslexia tendencies.

 706
 707
 708
 709
 710
 711
 712

713 Another interesting finding is Participants in the **LARF condition demonstrates a markedly higher completion**
 714 **rate** ($P_{LARF} = 98\%$) compared to those in the conventional condition ($P_{Conventional} = 85.7\%$) and the control condition
 715 ($P_{control} = 91.8\%$). A Fisher's exact test indicates that the difference in completion rates among the three conditions
 716 approaches is statistically significant, with a p-value of 0.069. This phenomenon illustrates that despite no additional
 717 requirement to treat this survey seriously, users in the LARF group still exhibit greater patience, aligning with the
 718 results of subjective evaluation where users perceive that LARF could enhance their reading confidence and patience.

reading challenges. In this section, we discuss the related research directions in the HCI community and promising real-world application scenarios that this work opens up. We also discuss the limitations of our work.

7.1 Future Work for HCI

Our work establishes the theoretical foundation and provides a software demo, but there are additional potential application scenarios for integrating LARF. As shown in Fig. 10, LARF can be incorporated into smart devices such as PCs, laptops, tablets, and even VR devices. The annotations in our demo and experiments are generated using OpenAI's GPT-4 API, however, LLM inference requires substantial GPU resources. Currently, the devices that can use LLMs for text annotation locally remain limited. Therefore, exploring how smaller models can accomplish this task and achieve optimal annotation quality is a meaningful topic for both the HCI and NLP communities. In existing research, we consider the NLP downstream topic Extract QA[43] aligns with our objectives.

While our work demonstrates the effectiveness of AI-based text annotation, how to make AI-generated annotations more accessible to users with reading difficulties is another direction the HCI community could further investigate. For example, prior studies have explored how the length of the highlighted text affects reading comprehension[44], and Tran et al. have examined the impact of data visualization colours on users with ADHD [45]. HCI researchers could explore ways to optimize the display of AI-generated annotations, such as the colour, brightness, or font of highlighted text. Additionally, we can investigate how to tailor annotations for different types of content, which may involve more complex prompts and task-specific fine-tuning.

LARF could also potentially be applied to subtitles in videos, live streams, and online courses. It is worth noting that research on such assistive annotations is still limited. For example, some studies suggest that the improvement in reading ability may result from the annotation process rather than the annotations themselves [?]. This raises an important question: could long-term reliance on AI-generated annotations, such as those in the LARF strategy, lead to a decline in memory or learning abilities over time? This is a topic worth further investigation. Additionally, dyslexia

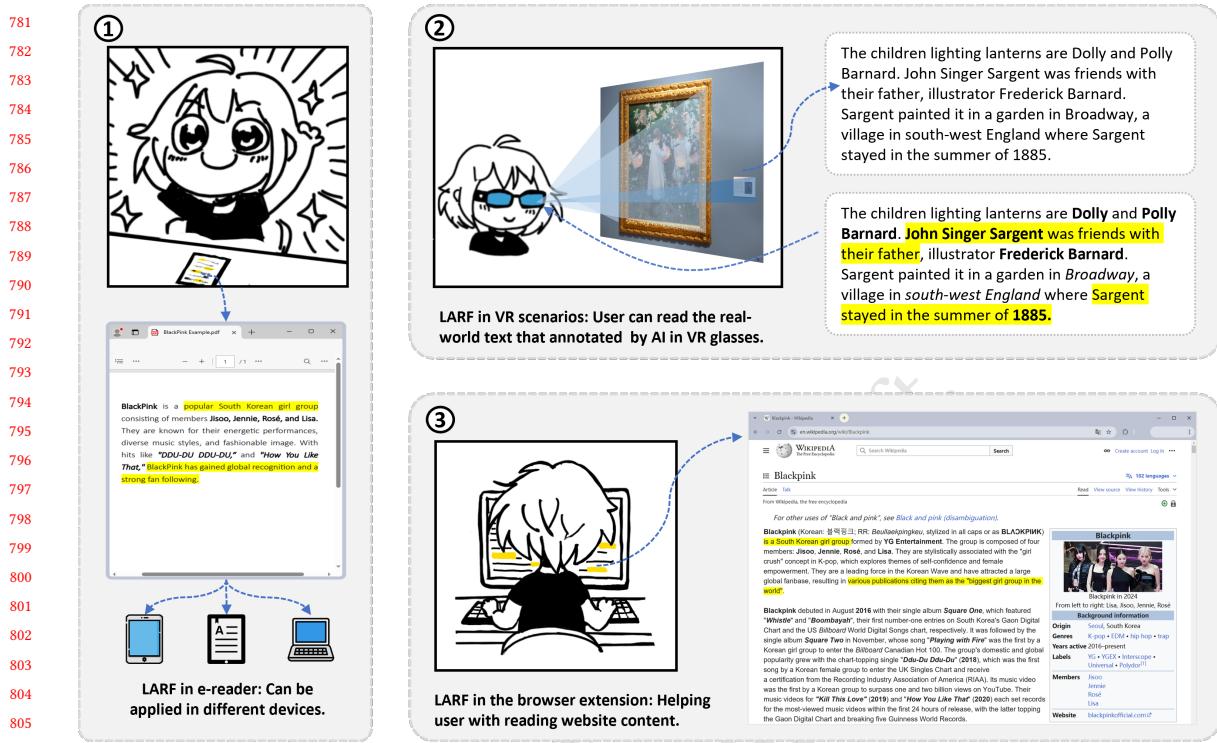

Fig. 10. Real-world application scenarios that can apply LARF. In the first subplot, the user is using an e-reader which is integrated with LARF, this device can be a tablet, a smartphone or a laptop. In the second subplot, the user is wearing VR glasses, looking at the “Carnation, Lily, Lily, Rose” by John Singer Sargent [42]. The VR headset with built-in LARF functionality helped annotate the description next to the painting, making it easier to read. In the Third subplot, LARF is integrated into a browser extension and helps the user reading the online content (the web page in the figure is the BlackPink item in Wikipedia[31].)

often co-occurs with other neurodevelopmental disorders, such as Attention Deficit Hyperactivity Disorder (ADHD) [46]. Future work could focus on whether AI-annotated text might introduce additional distractions for neurodiverse populations and how these distractions could be minimized.

7.2 Design Guidelines

In this section, we provide recommendations for future accessibility designs based on the results of our experiments using LARF. Users expressed a desire for customizable annotation settings (in Section 5.3 and Section ??). For example, in our software demo (refer to Appendix B), we implemented a text input box and a dropdown menu for selecting annotation types. This functionality could be integrated into e-readers or browser extensions. However, for applications in VR or on smaller screens (e.g., smartwatches), voice commands and gesture-based controls may be required. Users also wanted the ability to adjust the font size, spacing, and other text properties (Section ??), which is consistent with previous research [9]. Therefore, future designs should focus on integrating LARF together with existing accessibility features but not independently.

833 Additionally, in the follow-up experiment, two users expressed concerns about AI annotations, particularly regarding
834 privacy and annotation quality. To address these concerns, future designs should consider implementing local or end-
835 to-end models for inference to ensure user privacy. Furthermore, fine-tuning the models and using more sophisticated,
836 well-crafted prompts could improve the quality of AI-generated annotations.
837

838 7.3 Limitation

839 During the experimental process and software development, the study encountered several limitations:
840

841 To ensure that participants were not impatient with the questions (especially when the participants have dyslexia,
842 reading long content may cause cognitive load), our reading comprehension and recall tasks in the evaluation were not
843 set at high difficulty and we limited the number of questions. However, some of the questions have the potential risk of
844 being “too easy” for participants. This resulted in some evaluations observing only patterns but without significant
845 outcomes. We did not conduct a “random labelling group” in this article to exclude the influence of the placebo effect,
846 although intuitively such an effect should be small. As mentioned in Section 7.1, this study does not explore the
847 interaction among different types of annotations (e.g., bolding, highlighting), nor does it investigate which annotation
848 form would be most beneficial for users. Identifying optimal default prompts for user engagement is also not examined.
849 Adjusting the font size and colour is also achievable in HTML format, which is not discussed in this paper.
850

851 Previous work also shows that allowing users to set their own preferences can improve their reading accuracy
852 compared to the default setting [47]. So in our software demo, users can input what kinds of information and in what
853 types of presentation they want GPT-4 to annotate. However, in Experiment One and Experiment Two, the participants
854 only used the default prompt.
855

856 8 Conclusion

857 In this article, we introduce LARF, an AI-annotated text approach designed to enhance the reading abilities of in-
858 dividuals with reading difficulties and to address the limitations of traditional methods. Experiment One involved
859 150 participants with reported dyslexia, who completed a series of subjective and objective evaluations. The study
860 validated LARF’s effectiveness in improving dyslexic readers’ performance and experience, including recall of details,
861 reading comprehension efficiency, and engagement, outperforming the conventional technique (i.e., Bionic Reading).
862 Subsequent post hoc evaluation and Experiment Two further suggest that LARF is particularly beneficial for individuals
863 with severe reading difficulties. The follow-up experiment shows that LARF is also useful and satisfying in real-world
864 settings. In the discussion, we suggest future directions for AI-annotated text-assisted reading within LARF. These
865 insights contribute to the HCI community, delineating pathways for advanced assistive reading solutions.

A Experiments Details

A.1 Participants

Table 2. Participants Demographic in Experiment One

Gender	Age	Education		
Male	95	18-24	11	Less than high school 2
Female	50	25-34	56	High School graduate 58
Non-binary/Unknown	5	35-44	44	Bachelor degree (or currently in processing) 56
		45-54	26	Master degree (or currently in processing) 26
		55-64	12	Doctor degree (or currently in processing) 6
		65-74	0	
		75+	0	

Table 3. Participants Demographic in Experiment Two

Gender	Age
Male	83 18-24 12
Female	77 25-34 42
Non-binary/Unknown	0 35-44 49
	45-54 28
	55-64 19
	65-74 7
	75+ 3

A.2 Attention Check

In our attention check, participants are asked to answer the question where including the instruction that the correct answer is "Water". Participants who fail in this question will be marked as not focused.

989	In the modern era, explorers and archaeologists uncovered the secrets of the pyramid's chambers. The stories of Djoser,
990	Imhotep, and the countless hands that had shaped the monument were revealed, shedding light on the ancient world's
991	mysteries. To show that you have read the instructions carefully, please ignore the items below about the
992	explorers' findings and instead choose "Water". Based on the information in the preceding paragraph, which of
993	these objects did explorers find?
994	
995	o Gold
996	o Diamond
997	o Rosewood
998	o Water
999	o Stele
1000	
1001	
1002	
1003	
1004	

A.3 Dyslexia Checklist

Table 4. Dyslexia Checklist for Experiment One

Term	Scale	Description
Understanding	1–7	To what extent do you have difficulty understanding the meaning of sentences or paragraphs, even if individual words can be recognized?
Recognition	1–7	To what extent do you struggle to correctly and fluently recognize letters and words, which can lead to slow reading speed and misinterpretation of words?
Memory	1–7	To what extent do you struggle to remember what has been read, especially understanding longer texts or story plots?
Decoding	1–7	To what extent do you have difficulty blending letters into words and understanding word pronunciation rules, affecting reading fluency and comprehension?
Attention	1–7	To what extent do you have difficulty maintaining focus while reading for an extended period, leading to easy distractions?
Visual Disturbance	1–7	How frequently do you encounter visual disturbances during reading, such as letters or words appearing distorted, jumbled, or overlapping?

A.4 Recall Question

Two examples of our recall questions are given below:

Manuscript submitted to ACM

1041	Where is the Step Pyramid of Djoser at?
1042	o Saqqira
1043	o Saqqara
1044	o Saqqura
1045	o Saqqarua
1046	
1047	

1048	Which king in ancient Egypt does this article discuss?
1049	
1050	Please input your answer:
1051	
1052	
1053	

A.5 Retrieve Question

1054	An example of our retrieve question is given below:
1055	Please retrieve the article and provide as many details as possible (such as what specific data the article presents, what names appear, and the relationships between the characters and events, etc.)
1056	
1057	
1058	
1059	
1060	Please input your answer:
1061	
1062	
1063	

A.6 Default Prompt for GPT-4

1064	This prompt is used for Experiment One and Experiment Two, as well as the default prompt in our software demo (default model). It is designed to be used in general situations but not for particular articles. The detailed prompt is displayed below:
1065	
1066	You are an intelligent reader helper and you will be given a string of text in string format, please annotate it by adding tags following these instructions:
1067	
1068	
1069	
1070	1. Please annotate every date, number, location, and name of people or events in the paragraph by adding tags around them.
1071	
1072	2. Please highlight sentences and phrases in the paragraph that can summarize the core content of the paragraph or serve as a conclusion to the description by adding <mark> tags around them.
1073	
1074	3. Please underline sentences and phrases in the paragraph that are unusual or need to be particularly noted by adding <u> tags around them.
1075	
1076	4. You can add as many <mark>, , or <u> tags in one paragraph as necessary to highlight or bold important text.
1077	
1078	5. Please make sure to use and only use the 3 types of annotations above to annotate each paragraph of the text.
1079	
1080	6. Don't make the highlights or underlines too long or too often if it is not necessary.
1081	
1082	7. You are allowed to add only the above previously mentioned HTML tags, and that's the only change you can make to the text. YOUR OUTPUT MUST KEEP THE CONTENT OF THE ARTICLE THE SAME AS THE ORIGINAL ONE.
1083	
1084	8. Your output should only contain the marked text with added tags, which can be directly presented in HTML. Don't add anything else like "Here is your output" and so on.
1085	
1086	9. Keep the original language; i.e., if the context was given in Chinese, your output should be Chinese as well.
1087	
1088	
1089	
1090	
1091	
1092	2024-11-25 16:01. Page 21 of 1–28. Manuscript submitted to ACM

A.7 GPT-4 Evaluation Criteria

Here is the prompt for GPT-4 to give the score, we use a one-shot learning method to give GPT an example of a 6-point answer:

Please play the role of a rater and help me rate some answers. you will be given an article. Please read it, and you will be given some information about this article. I need you to score each item by their completeness and accuracy from 0 to 10.

A 0-point represents the entrance is very poor and basically contains no correct or important information and a 10 means the entrance is almost perfect.

A 5-point answer should have some details correct but misses or get some key information wrong, and the overall understanding of the article is partially correct.

A 7-point entrance should contain some correct details, such as the correct name, time, data, etc., or provide a not-bad summary of the overall article. However, it may be a lack of coherent logic or could miss some important information.

A 9-point entrance should contain most of the correct details, such as the correct name, time, data, etc., and it should also contain a logically coherent and accurate summary of the full text.

Here is the original article

ORIGINAL ARTICLE

Now you should directly give a score and the reason you give that score, and here is an example of 6-point entrance:

The entrance is: 10.5 m high, with 13 false doors, there were tombs made of mud and clay before stone pyramids, the third Egyptian dynasty was the first to build of stone.

And the answer is:

Score: 6

The entrance provides important details such as the height of the wall (10.5 meters) and the number of false doors (13). It also correctly mentions that tombs were made of mud and clay before the construction of stone pyramids and that the Third Dynasty of Egypt was the first to build with stone. However, it could have provided more information about the Step Pyramid itself, such as its final dimensions or its significance in Egyptian history. And its logic is not very coherent.

1195

1196

Table 6. Subjective Evaluation - All

Metrics	Question	Mean (SD)		Statistics (F(1, 95))	p-value
		Conventional	LARF		
Satisfaction	What is your overall satisfaction with this kind of presentation (highlights, underlines, or bold labels annotations/bold labels annotations) when you read articles?	3.76 (1.92)	4.42 (1.84)	2.994	.087*
Helpfulness	To what extent do you think you will continue to use this kind of presentation (highlights, underlines, or bold labels annotations/bold labels annotations) in future reading?	3.14 (1.76)	4.29 (1.99)	9.104	.003**
Intention for Future Use	To what extent do you believe the marks in the articles helped you concentrate on the key information?	2.94 (1.89)	3.92 (2.01)	6.111	.015*
Recommendation	To what extent will you recommend this kind of presentation (highlights, underlines, or bold labels annotations/bold labels annotations) to others?	3.18 (1.87)	4.42 (1.97)	10.034	.002**
Intention for Widespread Usage	Do you think this kind of presentation (highlights, underlines, or bold labels annotations/bold labels annotations) is suitable for widespread use in other contexts? For example, in special exam papers for people with reading disabilities, integrated into e-reader, or for online academic paper reading?	3.69 (2.10)	4.96 (1.96)	9.388	.003**

Notes:

- (1) Standard errors are in parentheses;
- (2) *p <0.1, **p <0.05, ***p <0.01

B Software Demo

The LARF software demo shown in Figure 11 is an interactive interface that users can open in a browser via a link. Users can copy and paste the text into the text box on the left, and by clicking the "Transfer" button, they can obtain the annotated text in the text box on the right. By checking the "Custom mode" option on the left, users can activate the custom prompt feature. When Custom mode is off, LARF will process the text using the same prompt as in the previous experiments. When Custom mode is on, users can enter the information they want to be annotated (such as the names of songs, members, and albums shown in the figure) and specify how they want this information to be annotated in the Key Information section below.

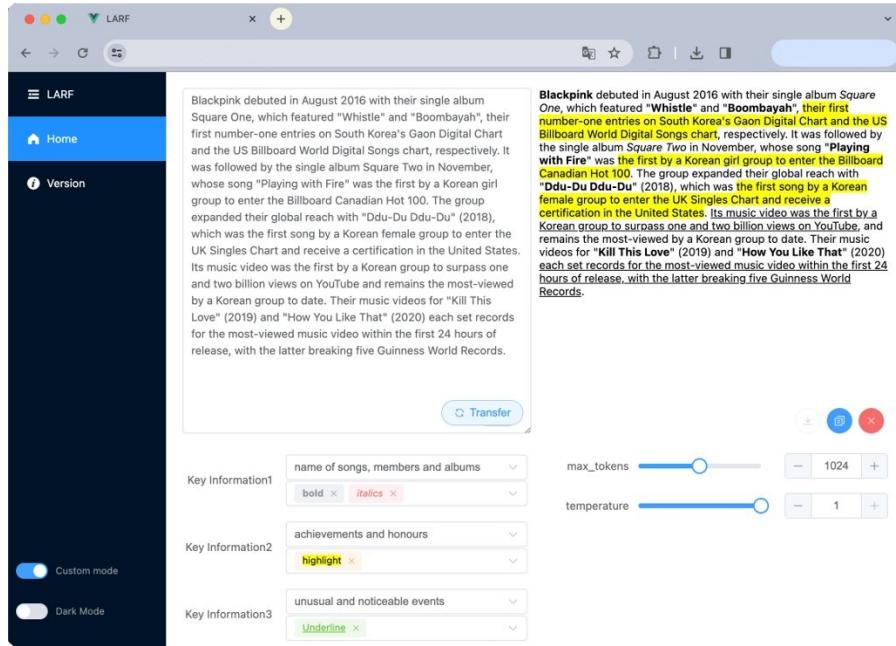

Fig. 11. The demo of the custom mode of LARF software application on PC.

C Supplemental Figures

C.1 Post Hoc Evaluation

The Post hoc evaluation for experiment 1: Given that individuals with dyslexia may encounter varying types and degrees of reading challenges, we categorized each symptom in the dyslexia checklist into "severe" and "mild". The red line depicted in the figure represents the performance of users facing more significant challenges in that specific item. The plot shows that LARF significantly improved recall, retrieval, and comprehension performance in individuals with more severe symptoms.

C.2 Bionic Reading

The Example of Bionic Reading is shown in Figure 14.

C.3 Follow-up Study

Received 20 February 2007; revised 12 March 2009; accepted 5 June 2009

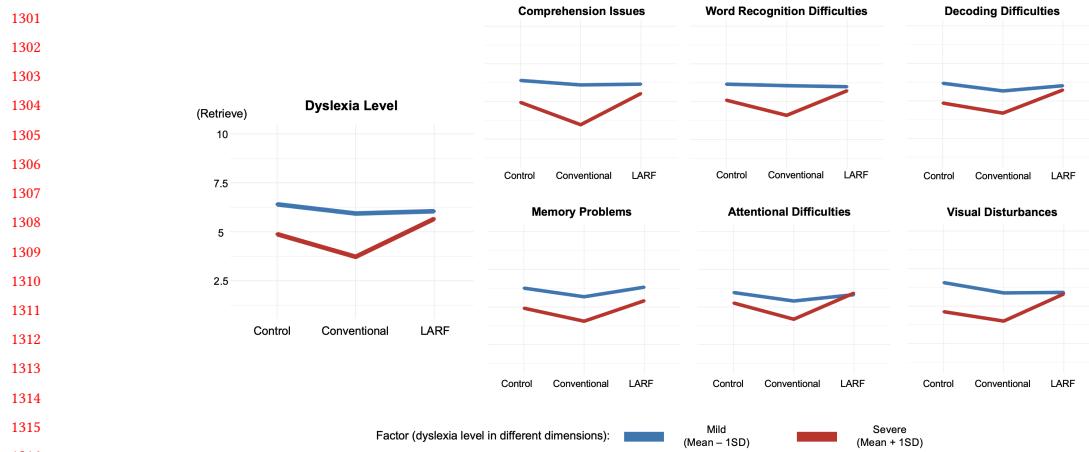

Fig. 12. Post hoc evaluation for retrieving performance. The y-axis represents the scores for retrieve, with a maximum score of 10. While in the group with mild symptoms, LARF did not exhibit improvement, it significantly enhanced users' retrieval abilities in the group facing more severe reading challenges, whereas conventional tools had almost entirely negative impacts.

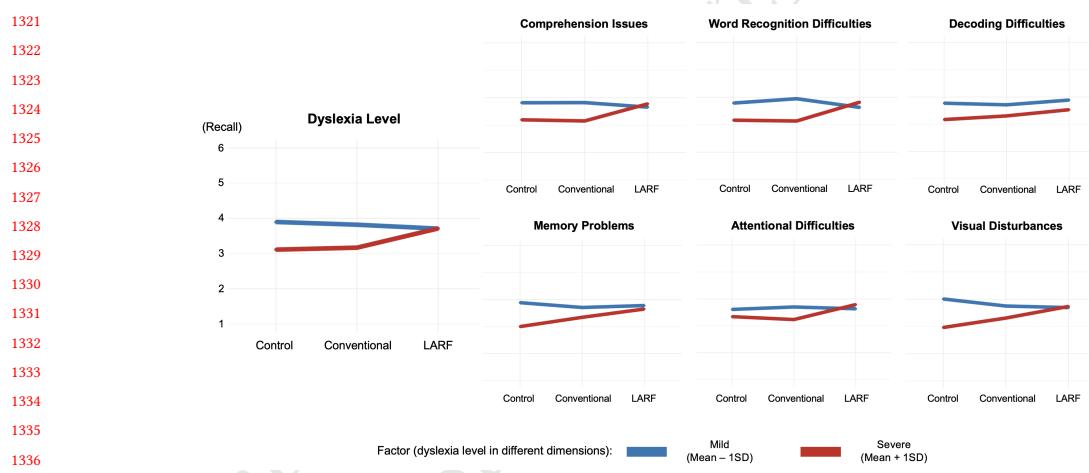

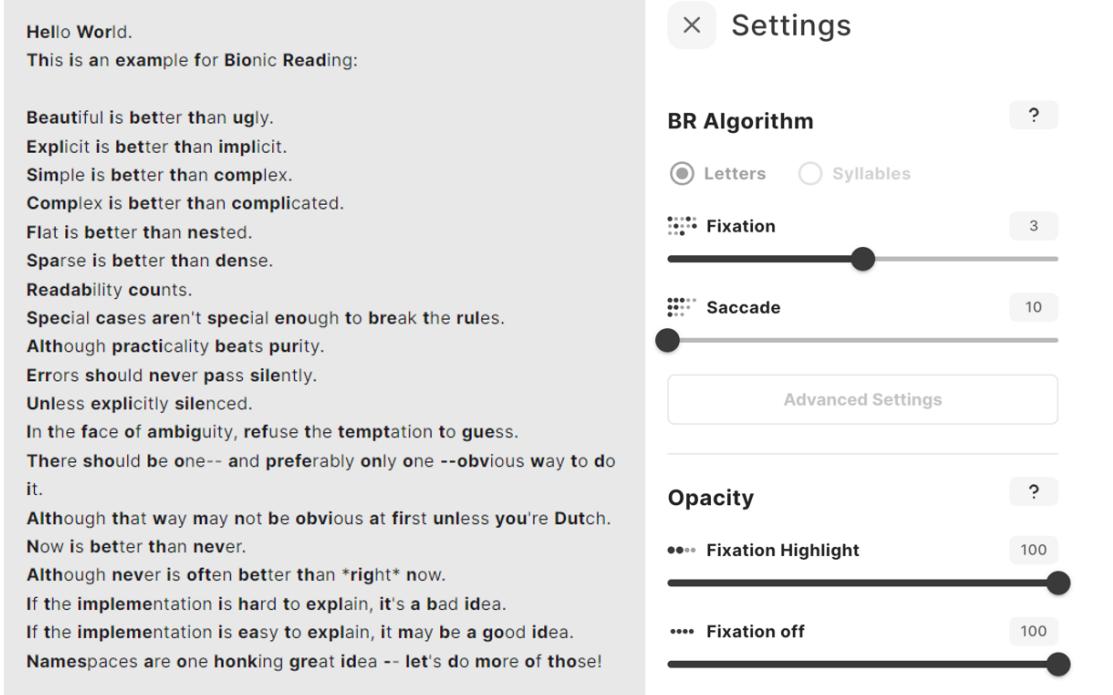

Fig. 13. Post hoc evaluation for recall performance. The y-axis represents the scores for recall, with a maximum score of 6. LARF similarly provided substantial assistance to the group with more severe symptoms, even surpassing the group with mild symptoms who also used LARF.

1353 Hello World.
 1354 This is an example for Bionic Reading:
 1355
 1356 Beautiful is better than ugly.
 1357 Explicit is better than implicit.
 1358 Simple is better than complex.
 1359 Complex is better than complicated.
 1360 Flat is better than nested.
 1361 Sparse is better than dense.
 1362 Readability counts.
 1363 Special cases aren't special enough to break the rules.
 1364 Although practicality beats purity.
 1365 Errors should never pass silently.
 1366 Unless explicitly silenced.
 1367 In the face of ambiguity, refuse the temptation to guess.
 1368 There should be one-- and preferably only one --obvious way to do it.
 1369 Although that way may not be obvious at first unless you're Dutch.
 1370 Now is better than never.
 1371 Although never is often better than *right* now.
 1372 If the implementation is hard to explain, it's a bad idea.
 1373 If the implementation is easy to explain, it may be a good idea.
 1374 Namespaces are one honking great idea -- let's do more of those!

The screenshot shows a text editor window on the left containing a series of aphorisms. On the right, there are two panels: 'BR Algorithm' and 'Opacity'. The 'BR Algorithm' panel has radio buttons for 'Letters' and 'Syllables', and sliders for 'Fixation' (value 3) and 'Saccade' (value 10). The 'Opacity' panel has sliders for 'Fixation Highlight' (value 100) and 'Fixation off' (value 100).

Fig. 14. An example of the result and parameters of Bionic Reading

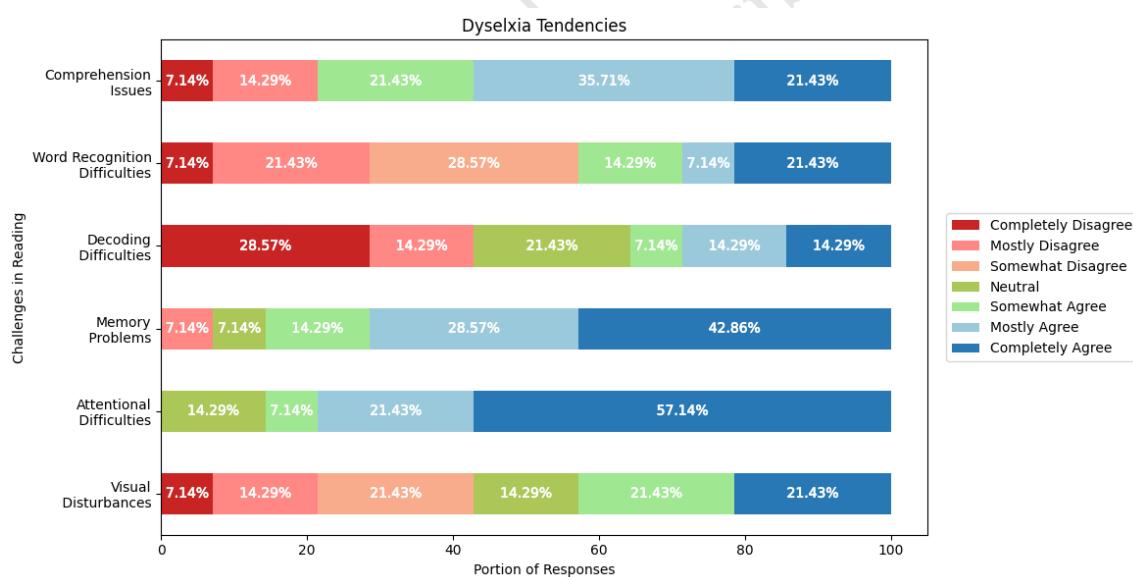

Fig. 15. The Dyslexia Tendency Scale includes participants' self-reported tendencies towards reading difficulties. The scale shows that 100% of the participants reported difficulties with attention deficit during reading, while only 35.71% of participants reported struggles with decoding

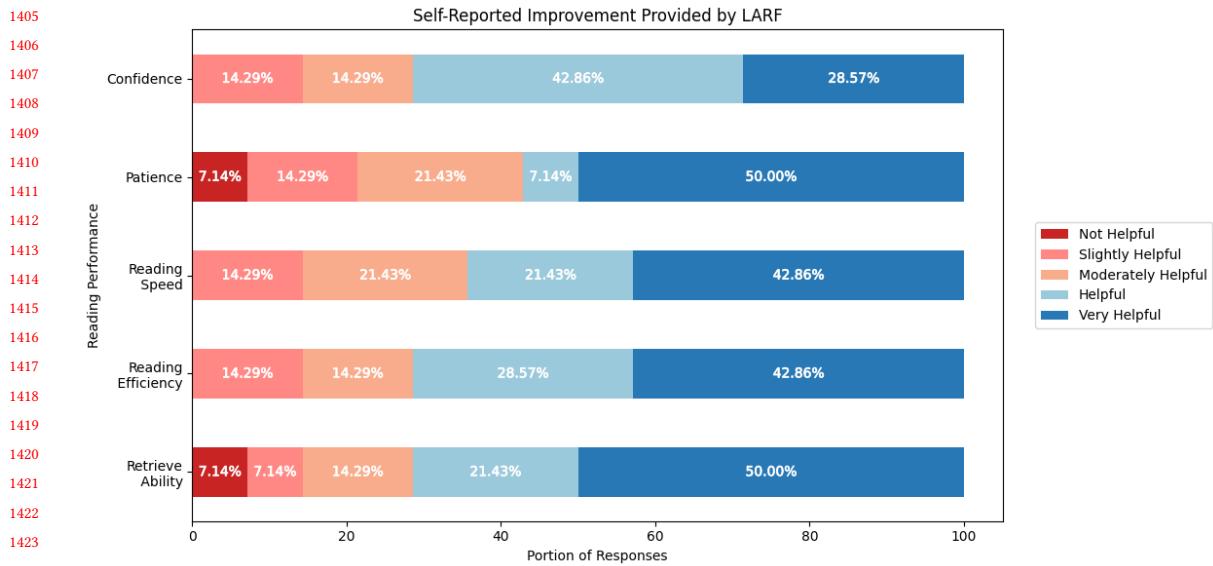

Fig. 16. Follow upstudy on users' experiences and performance improvements in reading with LARF. Most users believe that LARF enhances their reading speed, patience, efficiency, and ability to recall details.

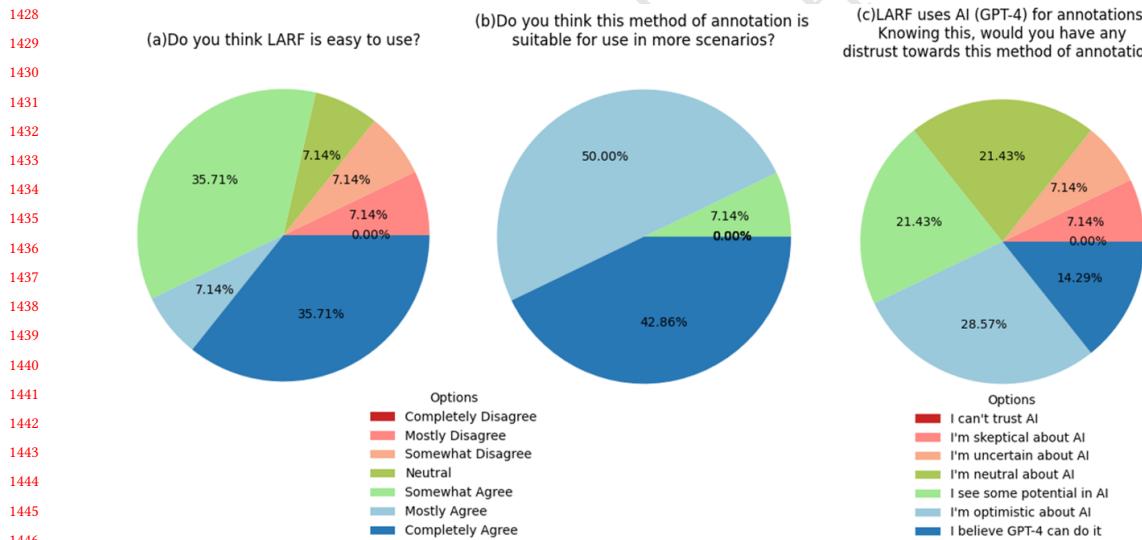

Fig. 17. (a)Surveying the ease of use of LARF, reveals that 50% of users think LARF is easy to use. (b) Regarding participants' support for the extension of LARF to other scenarios, shows that 100% of the participants expressed a positive view. (c) is about the trust level in AI annotation tools among users after being informed that LARF is generated by GPT-4, with 14.3% of the users expressing scepticism towards AI
